This is a silly story but while working on a project, I ran into a bug where the inner html was being copied over itself so it was displaying twice instead of just one time. The function was perfect. No typos and everything worked exactly as I wanted other than the information being shown two times over. There was nowhere that I had specifically told the code to do that. It was beginning to really frustrate me, when I realized there were one too many brackets at the end of my function. I had written the function that was giving me problems inside the function above it, causing it to be duplicated when clicking with the button associated with the first function. A very simple solution to something that

When working on the same project, I wanted to get certain data from an API that returned a lot of, to me, useless data. I was talking over my problems with someone nearby, they told me about a way to assign the data I want to an object and use a method where we assign that object as the parameters all in one get request. His method was super useful in sifting through the unwanted data and getting the data that I wanted to use. It is definitely something I will be using whenever using an API and using requests.
